24.To showcase the virtual machine migration based on the certain condition from one host to the other.

AIM:

To showcase the migration of a virtual machine from one host system to another based on a specified condition, demonstrating how the VM can be transferred while maintaining its configuration and operation.

PROCEDURE:

1. Install and open **Oracle VM VirtualBox** on the host system.
2. Create a virtual machine and install an operating system such as Ubuntu.
3. Configure the VM with suitable RAM, storage, CPU and network settings.
4. Start the virtual machine and verify that the operating system is working correctly.
5. Identify a migration condition, such as high CPU or memory usage on the source host.
6. Shut down the VM safely before transferring it.
7. Export the virtual machine from the source host as an **OVA/OVF** file.
8. Transfer the exported VM file to the destination host.
9. Open VirtualBox on the destination host and import the OVA/OVF file.
10. Start the imported virtual machine on the destination host.
11. Verify that the operating system, files and VM configuration are available after migration.
12. Compare the VM status before and after migration and confirm successful migration.

OUTPUT:

1.VirtualBox Manager — your VM visible in VirtualBox.

2.VM Settings — RAM, CPU, storage and network configuration.

3.VM Running — Ubuntu/Linux running inside VirtualBox.

4.Export Virtual Appliance — selecting your VM for migration.

5.Export Settings — destination and appliance settings.

6.Import Virtual Appliance — selecting the .ova file on the destination host.
